D3.7 Technical Specification (v2.1)

Project no. 636329
Project acronym: EfficienSea2
EFFICIENSEA2 – efficient, safe and sustainable traffic at sea

Funding scheme: Innovation Action (IA)
Start date of project: 1 May 2015
End date of project: 30 April 2018
Duration: 36 months

Due date of deliverable: N/A
Actual submission date: N/A

Organisation in charge of deliverable: OFFIS

“This project has received funding from the European Union’s Horizon 2020 research and innovation programme under grant agreement No 636329”.

1 Introduction

The Maritime Connectivity Platform (MCP) is an initiative towards providing infrastructural functions such as supporting the concept of a digital maritime identity. The concept behind the Maritime Connectivity Platform has been derived as “A communication framework enabling efficient, secure, reliable and seamless electronic information exchange among all authorized maritime stakeholders across available communication systems”, based on the IMO e-navigation strategy. This concept shall be enabled through an open and vendor-neutral platform and will allow for interconnecting heterogeneous software systems on board of various ship types, offshore structures or onshore.

Thereby the Maritime Connectivity Platform infrastructure does not aim to be used by mariners or ship owners directly, but to serve as a framework, providing standardized protocols and functions for service discovery, identity and role management and efficient messaging in a geographic context. Thus, enables easy development of new and innovative solutions for mariners and shore based end users.

For more information about the vision of the Maritime Connectivity Platform, the conceptual model behind and an informational user story, refer to the Deliverable “D3.2 Conceptual Model” [1]

1.1 Objectives of the document

The main goal of this document is to present a common understanding of the core components of the Maritime Connectivity Platform, between project partners in EfficienSea 2 as well as other related projects like STM1 or the Smart Navigation project initiated by the Republic of Korea.

Besides the identification of the MCP core components, this also includes the description and definition of how the Service Registry (SR) and Identity Registry (IR) work, how they interact with each other and how to use them in new maritime applications.

For this purpose, the document takes over different perspectives onto the MCP, related to its usage:

- The perspective of end users, like mariners,
- The perspective of service providers, who wish to publish their new developed services and
- The perspective of administrators in maritime organizations, who manage the identity of their employees or associated stuff.

---

1 STM Website: [http://stmvalidation.eu/](http://stmvalidation.eu/)
2 Overview

The Maritime Connectivity Platform is a service-oriented architecture that is composed of four core components, namely the Service Registry (SR), the Identity Registry (IR), an optional Communication and Messaging Component and the Maritime Connectivity Platform Demonstrator Component (MCDC). In addition, a fifth component called Almanac serves as offline copy of parts of the SR and IR, to allow access to relevant information in the absence of an internet connection.

1) Service Registry (SR):
The Service Registry is one of the Maritime Connectivity Platform core components (MC³) and is supposed to serve as a central reference point to provide and find services and thus to improve the visibility and accessibility of available information and services in the maritime domain. It’s best compared with a yellow pages phone book.

2) Identity Registry (IR):
The Identity Registry has the objective to enable an authentication of all maritime stakeholders in the context of the Maritime Connectivity Platform and thus increasing the security and reliability of communication. This goal is archived by providing a trustworthy infrastructure for identity authentication of maritime entities like human actors, services and devices.

3) Maritime Connectivity Platform Demonstrator Component (MCDC):
The Maritime Connectivity Platform Demonstrator Component serves as a reference implementation on how to use the other Maritime Connectivity Platform core components and can further be used by application developer (for example provider of ship equipment) to ease the usage of MCP functionality. For this purpose, the MCDC realizes some convenience functions, and takes the Network Roaming Device into account to ensure a maximum of connectivity.

4) Almanac:
The Almanac is an offline version of parts of the Service and Identity Registry, to be used if no stable internet connection is available for lookup in the online versions of SR and IR and thus to always allow access to the most relevant information during a journey.

5) Communication and Messaging Component:
The communication and messaging component shall ease the communication between the user, the Maritime Connectivity Platform Core Components and external services. This is done, by providing the capability to support seamless roaming on IP and non IP based communication channels and advanced message distribution, for example the Network Roaming Device from EfficienSea 2 (D2.7 Concept and specification for seamless roaming).
This component of the Maritime Connectivity Platform can be potential used onboard a ship. This depends on a former integration of for instance the Network Roaming Device in the technical equipment on a ship’s bridge. Moreover, the communication and messaging component also refers to the Maritime Messaging Service (MMS) as an upcoming core service of the Maritime Connectivity Platform. The MMS is currently under design as a shore-based messaging service for the provision of flexible communication between ship and shore by using multiple available communication links and for delivering geo-location based messages (geocasting).

As the Network Roaming Device and the MMS are components to ease and to improve the information exchange between communication members, these components are characterized as optional. The in this document described components are not restricted in their basic functionality if a IP based communication is established without using the communication and messaging component.

The following Figure 1 gives an overview over the components and how users and services interact with the Maritime Connectivity Platform.

![Figure 1 Overview over the Maritime Connectivity Platform components and their interconnection](image)

From the actor’s perspective, the actor uses the MCP Core Components, to authenticate himself within the Maritime Connectivity Platform. After he has been authenticated by the Identity Registry, he can use the Service Registry to discover descriptions and endpoints of services. On the right side of Figure 1, a service can be registered within the Service
Registry, by its provider. After a MCP user has established a connection, the service can use the Identity Registry to verify the identity of that user.

While the Maritime Connectivity Platform in general assumes an IP based connection, such an IP connection may not be available at any time, especially on board of an offshore vessel. In such a case, the MCP provides an optional Communication and messaging component, which is able to utilize different types of communication channels (e.g. by using the Roaming Device). In case the user is not able to establish a stable internet connection, even with the help of the communication and messaging component, the actor also got the opportunity to lookup services and identities of other maritime actors, using the Almanac component, as indicated on the most left part of Figure 1. This offline copy of the MCP Core Component, will be synchronized, if a stable internet connection is available.

As described above, the Maritime Connectivity Platform supports its MCP users, service user as well as service implementers with means for communication, using the optional Communication and messaging component.

Figure 2 Logical perspective of communication and messaging in the Maritime Connectivity Platform

Figure 17 describes a conceptual view on the communication and messaging inside the Maritime Connectivity Platform. Thereby the upper part of the figure describes the user’s
perspective of the communication, whereas the lower part describes the technical perspective that is hidden as much as possible by the Maritime Connectivity Platform Demonstrator Component.

The communication infrastructure supports three types of communication scenarios, indicated by the arrow color in Figure 17.

1) IP-based communication (blue lines in Figure 17):
The connection between client and services is instantiated using an existing internet connection.

2) Roaming communication (black lines in Figure 17):
The connection between client and service is done, using a roaming device which routes the requests for connections to the Maritime Connectivity Platform, via a suitable IP or non-IP connection. This solution also participates from a QoS that can be provided by the roaming component.

3) Maritime Messaging Server (green lines in Figure 17):
Client (e.g. MCDC) uses the Maritime Messaging Service (MMS) to access a service in the Maritime Connectivity Platform. The MMS regulates the access request and connects to available communication channels with a defined QoS. The communication channel either is IP-based or benefits from the Network Roaming Device (black-green lines in Figure 17). In addition, the MMS is able to queue incoming and outgoing messages for the case, no stable connection could be established with any of the available devices.

A more concrete description about the realization of these approaches in different projects are further described in chapter 3.5 and chapter 3.7

2.1 Maritime Connectivity Platform structure
This section gives a holistic view on the Maritime Connectivity Platform approach using the Maritime Architecture Framework (MAF) to show the structure and relation between intended functions of the Maritime Connectivity Platform in context with Information- and Data models as well as with used protocols and physical- and software components.

The Maritime Architecture Framework is a framework to support the development of system architectures by representing technical, functional and organizational aspects of a systems structure. It uses a structural framework to enable a visualization of those aspects in relation to each other and with the structure of the maritime domain [2].

2.1.1 Maritime Connectivity Platform components
The MCP’s overall goal is to support a safe and reliable seafaring by facilitating information exchange across various communication channels, either IP-based or non IP-based.
The development of this approach within the EfficienSea2 project focuses mainly on the development of the key components Service Registry and Identity Registry (see Figure 3 below). With these technical services, the users are enabled to access any kind of service, which is registered in the Service Registry either via the Maritime Connectivity Demonstrator Component (MCDC) as a “add-on” component to maritime systems (e.g. an ECDIS) or through a shore based application (e.g. the web-platform MC Portal\(^2\) for managing services and identities of organizations in the Maritime Connectivity Platform, developed in an external project).

The communication between ship and shore is granted via a Network Roaming Device, which is currently specified in D2.7 [3] and D2.8 [4] in combination with existing components (AIS-Receiver and LAN-/WLAN-router etc.). The Network Roaming Device can be configured by the users through the MCDC to establish a specific communication link either via LAN / WLAN or other communication channels such as a radio waves.

\(^2\) https://portal.maritimecloud.net
2.1.2 Maritime Connectivity Platform communication

The communication between the listed components in the previous subsection is established by using the following communication methods (see Figure 4). While using VHF for communication via AIS-Receiver, the common “Maritime Connectivity Platform” communication, either to the Service Registry or Identity Registry or other services, is done via TCP / IP based approach with web service technologies such as SOAP and REST. Furthermore, a Roaming Device enables the ship-side infrastructure to offer an additional serial interface to maritime components such as an ECDIS.
2.1.3 Maritime Connectivity Platform information exchange

The various Maritime Connectivity Platform components are used with different data models (such as data formats or APIs). As displayed in Figure 5, the Service Registry and Identity Registry provides their own API and data formats (sketched in section 3.1) to communicate with any kind of MCP services or with the MCDC as ship-side Maritime Connectivity Platform component. Router and Roaming Device as well as AIS-Receiver are “routing” the information flow via TCP / UDP or CAN Bus to specific data facilitating technical services. The communication means of the different components enables the use of custom data formats of not yet defined Maritime Connectivity Platform services via REST / SOAP.
2.1.4 Conclusion
This subsection introduces a holistic view on the Maritime Connectivity Platform based on the sub-sections. The figure below takes the components, information aspects and communication methods as listed in further subsections and establish a layer model to contextualize them to each other. Furthermore, the top-layer shows the intended functions for the items in the underlying layers. This enables the view from perspectives on the Maritime Connectivity Platform structure (see Figure 6).

Figure 5 The data formats used in the Maritime Connectivity Platform
This deliverable describes in detail the different aspects of the Service Registry, Identity Registry as well as the MCDC in relation with the overarching maritime structure as described above, in the sections below. It starts with a conceptual description containing use cases as well as intended data models for the key components (Service Registry and Identity Registry) before the sections 3.4 and 3.5. concentrates on the dedicated functionalities of those components. The technical specification ends up with a description of the functional design in section 4.
3 Conceptual Description

3.1 User and Use Cases
This section will describe the functionality of the Maritime Connectivity Platform core components (MC³) from the perspective of an MCP user.

Table 1 Possible user roles for the Maritime Connectivity Platform

<table>
<thead>
<tr>
<th>Role</th>
<th>Description</th>
<th>Rights</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service User</td>
<td>Regular users of the Service Registry.</td>
<td>Users of this role are allowed to lookup the service registry for service specifications, designs, instances. They can also be found (and authenticated) within the Identity Registry.</td>
</tr>
<tr>
<td>Service Administrator</td>
<td>Role for administration of services in the Service Registry.</td>
<td>Users of this role are allowed to register service specifications, designs, instances and to modify such registrations.</td>
</tr>
<tr>
<td>Organization Administrator</td>
<td>Role for administration of identities in the Identity Registry</td>
<td>Users of this role are allowed to register and modify entities (User, Services, Devices) in the Identity Registry.</td>
</tr>
<tr>
<td>Service Registry Administrator</td>
<td>Role for administration of the service Registry.</td>
<td>Users of this role are allowed to administrate user roles and access rights in the service registry. Note that this only covers the access rights for accessing the Service Registry. Not to be confused with the rights for accessing other services: such access rights administration for other services is not performed in the Service Registry, but is in the responsibility of the other services themselves.</td>
</tr>
<tr>
<td>Identity Registry Administrator</td>
<td>Role for the administration of the Identity Registry</td>
<td>Users of this role are allowed to administrate user roles and access rights in the Identity Registry</td>
</tr>
<tr>
<td>Service Registry Super User</td>
<td>Local super user of the Service Registry</td>
<td>This user is not published. Allows to manually create Service Registry Administrator users.</td>
</tr>
</tbody>
</table>

Since both, the Identity Registry as well as the Service Registry can be seen as a service, the Organization Administrator and the Service Administrator inherit the roles of a Service User. In addition, they have to perform Service User tasks, in order to fulfill the administration tasks (see section 3.3.2). The Service Registry Super User and the Identity Registry Super User are local administrators, which are only relevant in the company, hosting either the Service or Identity Registry. Thus their roles will not be further considered.
Figure 7 identified use cases for the Identity and Service Registry

Figure 7 describes the identified use cases for the MCP components IR and SR, while Table 2 gives a short description as well as a link to those sections that handle the use case in more detail.

“This project has received funding from the European Union’s Horizon 2020 research and innovation programme under grant agreement No 636329"
3.2 Information Model

Figure 8 Mind map for the data model of the Maritime Connectivity Platform

Figure 8 gives an overview about the most relevant information, stored in the Service and Identity Registry.

3.2.1 Service Registry
As it can be seen on the left side of the picture, the Service Registry contains a list of “SR_Services”, which should not be confused with the “IR_Service” of the Identity Registry. Such an SR Service is further subdivided into a Service Specification, a Technical Design and a Service Instance Description.

1) Service Specification

The service specification describes one dedicated service at logical level in a technology-agnostic manner.
Among other, the Service Specification contains a list of freeform keywords that describes the service.

2) Technical Design

The technical design describes the details of a specific service specification. Thereby the technical design provides information about the actual realization of the service with a dedicated technology decision (depicted in Figure 8 as “Capabilities”).

3) Service Instance Description
A service implementation (implemented according to a given technical design) may be deployed at different locations by different service providers. For each such service instance a service instance description shall be provided. Among others, the service instance description contains the endpoint for the service implementation and thus how to access the service. In addition the description optionally contains an area of application, which is the area the specific service implementation is valid for. For example: A VTS – Service like Jade-Traffic that is only valid inside the Jade-fairway.

The relations among these three elements are visualized in Figure 9.

![Figure 9 Distinction between Service Specification, Service Technical Design and Service Instance](image)

For more information about the structure of the Service Specification, Technical Design and Service Instance Description, please refer to Deliverable “D3.6 - Service Documentation Guidelines” [5].

### 3.2.2 Identity Registry

The Identity Registry, as shown in Figure 8 is composed of multiple organizations. Each organization can contain different types of maritime entities, such as human users, vessels, devices and services.

At this point, it’s important to know that the organization a maritime entity belongs to does not necessarily is the owner (or employer) of the corresponding entity, but need to be able to prove its identity.

Each of these maritime entities contains a maritime resource name (MRN), as described in [6] as unique identifier.
1 **Organization**

In the Maritime Connectivity Platform an *organization* is an entity, such as an institution, company or an association that has a collective goal and is linked to an external environment. Examples, include international organizations such as IMO, IALA, and IHO. National authorities such as US Coastguard, Swedish Maritime Administration. Local authorities such as VTS-Oeresund, Port of Rotterdam, Hong Kong SAR. Or commercial companies such as Transas or Maris.

2 **Users**

Users mainly refers to human users. Human users differ from other actors in that they typically use a username/password to login which implies a different interaction pattern with the identity registry then say communication between vessels.

3 **Services**

Services refers to digital services, as described above. For example, a weather service that is available to other services for machine to machine communication. Services needs to be registered in such a way that it can successfully authenticate users.

4 **Vessels**

Vessels describes any floating object used for the carriage of people or goods. The main need for registering vessels in the Maritime Connectivity Platform is so that digital authentication certificates can be issued for them. Thereby enabling secure communication between vessels as well as digitally signing of documents. Users might also use these authentication certificates for other purposes. The important thing is that the functionality is there. As part of the authentication certificate of a vessel its name, MMSI number, IMO number, call sign and possible other attributes is included in the header of the authentication certificate.

5 **Devices**

Devices can be any number of entities that is not covered by the other entity types. It could for example be a lighthouse, an ECDIS or a server that needs to be able to authenticate itself. For example an ECDIS system.

As both, the SR and the IR contain a “Service” element, the Identity Registry service represents an identifiable service that links to a service implementation (e.g. a service instance description) in the Service Registry. In this case, both service representations share the same maritime resource name (MRN). On the other hand it’s not required that a service is registered within the Identity Registry to be registered in the Service Registry.
3.3 Functionalities of Service Registry
The functionality of the service registry is separated into two areas 1) the discovery of services and 2) the management of those.

3.3.1 Service Discovery
Main objective of the Service Registry is to enable the discovery of maritime services for a large number of users. Those users may be human actors, like a nautical officer or artificial devices, an ECDIS or a weather service.

As described in the following Figure 10, the process of finding service instances is split into 3 successive steps, together with one optional step, performed on the user’s side.

![Business Process FindService Diagram]

As indicated through the different input values for the discovery activities, services may be searched for different criteria’s, like keywords, locations, organizations or combinations of those. The result of each discovery activity is a list of service documentations, which serve as input for the next step. In addition the used technical equipment can perform filtering (“filter compatibility” in Figure 10) with respect to its own capabilities. Those capabilities may contain, but are not restricted to, the communication means (REST / SOAP).

Figure 10 describes an uninformed search, e.g. there is no additional information present at the beginning. If on the other hand prior knowledge about for example the Service Specification is available, the “Discover Service Specification” step may be omitted. Same goes for the Technical Design.

Taking into account that the Service Registry may be used either by humans or machines, the Service Registry offers two approaches to discover services, a manual discovery for human users and a machine to machine discovery process, as shown in Figure 11 and Figure 12.
This project has received funding from the European Union’s Horizon 2020 research and innovation programme under grant agreement No 636329.

Both processes use the sub process “FindService” (as described in Figure 10) that contains the actual realization of the Service Registry’s functionality.

The main difference between the manual and the automatic service discovery process is the need of unique answers from the service registry, in case of automatic discovery. This is archived through a “spatial exclusive” flag that is, for this service specification there is only one combination of service specification and technical design, valid within a defined area / location. To ensure the uniqueness of services (e.g. who is allowed to set the exclusive flag) appropriate governance processes have to be established in the future. If no such governance process exists or does not apply for a specific service, the filtering through the preconfigured rules has to ensure that exactly one service is selected.
3.3.2 Service Management

The following Figure 13 shows the activities that have to be performed, when a Service Specification, a Technical Design or a Service Instance Description shall be registered within the Service Registry.

![Activity Diagram for management of services in the service registry](image)

Figure 13 Activity Diagram for management of services in the service registry. Green activities are manual activities, not handled here.

Here the “user – activities” (marked through the user icon) describe the creation of the required documents, which is not further considered here. Furthermore the user may enter the described workflow at different entry points, depending on the available information. That is, if the technical design to be implemented is already known, the service implementation may be created and published without the previous steps.
3.4 Functionalities of Identity Registry

Besides discovery and management of services, within the Maritime Connectivity Platform, there is a need to authenticate all maritime resources before providing or using a service. This is done by the Identity Registry.

As the Service Registry the Identity Registry can be subdivided into the two sections as well. This two sections include the management of identities and the authentication of maritime resources.

3.4.1 User Federation

The Maritime Connectivity Platform Identity Registry uses a federated system of identity providers, to manage the maritime identities. Federation is the means of linking distinct identity management systems to a person’s electronic identity and attributes. For example, a shipping company might expose all their users in LDAP or Active Directory to the Maritime Connectivity Platform in such a way as they appear as MCP users. Thereby bypassing the need to manage their users directly in the Maritime Connectivity Platform. This also means that the Maritime Connectivity Platform is not responsible for management of users. In practical terms, federation means that users asked to authenticate in the Maritime Connectivity Platform will be redirected to a login webpage supplied by their organization where they can login using their organizational id. An identity provider has to be compliant with the OpenID Connect\(^3\) protocol, to be compliant with the Identity Registry.

3.4.1.1 Security

The federation approach allows each registered organization to manage their users according to their own security and privacy policies. This significantly increases for example the security of user data. However the identity broker, provided by the Maritime Connectivity Platform Identity Registry, serves as “man in the middle” and thus becomes an issue regarding the reliability of the Identity Registry. If the identity broker is not available for any reason, none of the users or services within the Maritime Connectivity Platform would be able to authenticate themselves. Within the EfficienSea 2 testbeds this issue will not be addressed at first. For a later, operational operation, the usage of several redundant identity brokers is considered, to accomplish a failsafe authentication.

\(^3\) [http://openid.net/](http://openid.net/)
3.4.2 Identity Management
As shown in Figure 8 each maritime entity is bound to a trusted organization. This has to be considered in the process of creating new identities (see Figure 14).

![Diagram of Identity Management process](image)

**Figure 14 Process to create a new maritime identity in the Identity Registry**

Figure 14 is using the same graphical notation as Figure 13, in terms of “user-activities”. E.g. the processes of creating an organization, or creating an entity is the collection of all required information, to be feed into the Identity Registry and is done by an Identity Registry Administrator (see Table 1).

Like in case of the Service Registry, may different starting points can be used, if prior knowledge is available. If for example the organization is known, its identifier has not to be determined using the “Search Organization” activity.

3.5 Maritime Connectivity Platform Demonstrator Component
The Maritime Connectivity Platform Demonstrator Component (MCDC) is meant as a reference implementation, to demonstrate the correct usage of the identity and service registry, as well as the offline copy of those. For this purpose, it will provide an easy to use interface for application developers, who want to interface their products with the Maritime Connectivity Platform as described in Figure 15.
Figure 15 Technical overview over the components of the Maritime Connectivity Platform and the interfaces for service users.

The following Figure 16 shows an early consideration, for the internal structure of the MCDC, which can be decomposed into the following five components.
Figure 16 internal structure of the Maritime Connectivity Platform Demonstrator Component

- **User Configuration:**
  This component stores user preferences on how to access the Maritime Connectivity Platform. These user preferences, can be manipulated by the user and contain for example information about service provider, the user (or his organization) has contacts with.

- **Discovery Logic:**
  The discovery logic interacts with the Service and Identity Registry, to discover service instances for the user. Thereby the Discovery Logic calls the Service Registry API in the correct order, for the current discovery operation, taking into account preliminary knowledge like already known service specification ids (see below).

- **Filter Logic:**
  The Filter Logic is used to filter out results, from the Service Registry, which are of no interest for the user. At this point the Filter Logic interacts with the user preferences as well as with discovery options.

- **Almanac Facade:**
  The Almanac Facade is used to decide whether to use the online or the offline version (Almanac) of the Service and Identity Registry. Depending on the result the request is either forwarded to the Almanac component or to the external service / identity registry using the Roaming Facade.

- **Roaming Facade:**
  The Roaming Facade is used to communicate with the outer world with the assistance of the Roaming Device, developed in EfficienSea 2 (Work package 2). For this...
purpose requests to external sites will be passed through the Roaming Facade to the Roaming Device. In addition, the Facade is able to configure the Device according to the user’s requirements, by making use of the User Configuration component.

3.6 Almanac
The Almanac is an offline copy of the service and identity registry, to be used, if no stable internet connection could be established. It will provide the same interface as the real Service and Identity Registry but runs on a local server on board of a vessel. At the time, writing this document, the Almanac has not been fully specified.

3.7 Communication and messaging
This section provides an overview about the advanced development of the Maritime Connectivity Platform for practical usage. It contributes to the currently undertaken and planned efforts within the three projects ES2, STM and Smart Navigation for harmonization of the different components of the Maritime Connectivity Platform for a future integration into existing maritime equipment onboard and ashore.

As described above, the Maritime Connectivity Platform supports its users, service consumer as well as service implementers, with means for communication, using the communication and messaging elements.

Figure 17 describes a logical view on an envisioned communication and messaging inside the Maritime Connectivity Platform, using the Network Roaming Device (RD), the Maritime Connectivity Platform Demonstrator Component (MCDC) as well as the Maritime Messaging Service that is currently under development. Besides a direct internet connection, there are two ways for information exchange within the Maritime Connectivity Platform communication infrastructure:

- Communication using the MCDC
- Communication using the MMS
The communication means are described in the sections below.

3.7.1 Communication using the MCDC

The MCDC is acting as the interface between a client application (e.g. an ECDIS) and the Maritime Connectivity Platform environment. Its main intention is to be used onboard a ship. A usage as part of a shore-based station is nevertheless possible. The MCDC is currently under development as a reference implementation for demonstration purpose how to integrate the Maritime Connectivity Platform into existing environment. An own implementation of the MCDCs functionality into a client application by the manufactures is envisioned.

![Diagram](image)

**Figure 18. IP-based communication using MCDC and RD**

As seen in Figure 18, the client application, like an ECDIS, sends a request for MSI to the MCDC. The MCDC configures in an appropriate way the Network Roaming Device to...
connect the Service Registry and Identity Registry. After authentication, the Service Registry can be used to discover endpoints of related MSI service instances. Via the client application, a service instance is chosen. The client application sends the request for information exchange with the specific MSI service instance including payload to the MCDC. The MCDC configures the Network Roaming Device to establish an IP-based communication with the service instance via appropriate communication means. After a connection is established, the MCDC forwards the message and provides the interaction between client application and the related service instance.

3.7.2 Communication using the MMS
The MMS in general is acting as a kind of roaming component on application level. It provides functionality such as geocasting and multicasting and delivers messages based on application specific semantics, namely and mainly based on Maritime Resource Name (MRN). The MMS consists of two main components: the MMS Client Component (MMSCC), which is located on service consumer side as element inside the MCDC and the MMS Shore Component (MMSSC), which is the shore based service that executes the functions of the MMS. The communication is partly like the pattern introduced in section 3.7.1.

As seen in Figure 19, a vessel is equipped with a suitable service client application (e.g. an ECDIS), which is connected to the MCDC. This component includes an additional (sub-) component, the MMS Client Component (MMSCC). In case of using the MMS for communication between service client application and a service instance or Service Registry / Identity Registry, the MMSCC in the MCDC is used.

So, the client application sends a service request to the MMS Client Component on board. The MMSCC forwards this request via the Network Roaming Device to the MMS Shore Component (MMSSC). Based on MRN and additional application semantics that may be contained in the service request, the MMS Shore Component routes the request to the corresponding service instance. The service then sends the answer to that request back to the MMS Shore Component. In the MMS Shore Component, this answer will be stored in a queue but not sent directly back to the requesting ship. This is because, in between the ship may have lost the internet connection. Instead, the MMS Client Component on board the vessel will poll the MMS Shore Component for new messages to be delivered to the client applications on board, if a connection is established. Whenever there is a new message on shore available the MMS Client Component will pick it up and deliver it to the client application. From the perspective of the client application on board, this polling will be transparent. The client application will only send a request to the MMS Client Component and when the answer is received, it will get it from that component.

This approach has the advantage that on the one hand, the loss of connection is covered and on the other hand there do not need to be different service implementations depending on whether a service makes use of the MMS or not.
However, it is important that there are some requirements to be fulfilled to make the use of MMS feasible.

1. A service using MMS functionality must provide an appropriate interface. E. g. if the geo-casting functionality of the service shall be used, the corresponding service resp. service instance needs to provide Geo-Information in its provided data. Otherwise, the MMS cannot decide where to send the information.

2. The MMS client component on boards needs to tell the own casting parameters to the MMS Shore Component. E. g. the MMS Shore component needs to know where a specific vessel is in order to decide, whether it shall deliver a message to it or not.
It is important to understand that the MMS can, from the perspective of a service provider, be seen as a library providing function that have not be implemented by the service provider itself any more. E. g. if a service provider wants to provide geocasting functionality, it can either implement it in the service instance directly requiring the registration of users with their geo-location and requiring to implement a corresponding filtering algorithm or to simply use the MMS for doing it.

From the perspective of the service consumer the MMS can be seen as a simple casting service. This means that due to the use of the MMS the service interface of the request service behind will not change. So, the client application will always request the same service interface no matter whether this is done directly or via the MMS.

The main functionalities provided by the MMS are the following:

- **Geocasting**: Information will be delivered based on the geographical position of a service consumer. E. g. vessels will only receive MSI for the region they are in.
- **Multicasting**: Information will be delivered base on application specific criteria. The configuration can be done by service providers (Which parameters can be used for discrimination?) and service consumers (Which data am I interested in?) within the MMS.
- **Publish-Subscribe**: The MMS can manage subscription lists for specific services. This functionality can be combined with the above functionalities.
4 Functional Design

The following section will provide an overview over the available interfaces and interactions for the MCP Core Components, namely Service and Identity Registry.

Thereby Figure 20 shows a subset of public available interfaces of the core components, as well as an assignment to the user roles defined in Table 1. The interfaces are described in more detail in the following sections 4.2.1(SR) and 4.2.2 (IR).
4.1 Data types
The following to Figures (Figure 21 and Figure 22) give a brief overview about important information, stored within the Service and Identity Registry.

![Diagram of Service Registry classes and relationships]

**Figure 21 Data types for Service Registry**

The Service Registry contains the Service Specification, Technical Design and Instance Description, as described in Deliverable D3.6 (Service Documentation Guidelines [5]). Those documents shall be available in a human readable and a machine readable format. For a complete description of the Service Registry Data Model, refer the Service Documentation Guideline.
The Identity Registry is organized around an organization. Each maritime entity has to be associated to exactly one organization which is able to proof its identity. In addition each maritime entity as well as each organization can own certificates, used for authentication. Certificates used within the Maritime Connectivity Platform are based on the X.509 standard for M2M communication. For more information about the used certificates refer to the article Identity Management and Cyber Security [7].

---

4.2 Interfaces

4.2.1 Service Registry API
The service registry supports the following API.
The first column of the table contains the related area of the SR that is modified with the API call. The second column contains the API call, whereas the third column contains the desired result.

4.3 Interactions

4.3.1 Authentication
One of the main functionalities of the Identity registry is the authentication of users. The following Figure 23 shows the interaction between a human user and the responsible parts within the Identity Registry. The figure also contains the required interaction to validate a security token, as it is provided as result of a login activity.
The Identity Registry uses a federated system approach, where the IdentityBroker is used as centralized mediator. The Broker knows all registered organizations and can redirect the login request to a specific IdentityProvider. The authentication is then performed, depending on the capabilities of the used identity provider. This centralized approach is intended to ease the usage of the Identity Registry, by providing only one entry point for Identity Management and authentication.

Besides the login with username and password (as shown in Figure 23), the Identity Broker also supports the login, using a certificate. The corresponding sequence diagram is shown in Figure 24. When using a certificate for login, the Identity Broker validates the provided certificate and returns an OpenID token. Thus an external service do not have to implement two validation methods; token based authentication and certificate authentication.
4.3.2 Management
Within the Maritime Connectivity Platform Identity Registry, each maritime entity (Vessel, User, Device or Service) is associated to an organization that is able to verify the identity of the entity.

The creation of a new organization is currently done manually by a not yet fully defined authority (for the EfficienSea 2 testbed, the DMA takes over this part). The authority is responsible to check the trustworthiness of the requesting organization and register it within the Identity Registry. The corresponding sequence diagram is shown in Figure 25.

In Figure 25, the Identity Registry performs some additional steps, like checking the authorization of the current user, who has to be an Identity Registry administrator. If the authorization has been confirmed, the internal structures for the organization will be created.

In addition an organization administrator (see Table 1) for the new organization is created. This organization administrator will be able to register additional maritime entities for the new organization, as described in the following section (section 4.3.3).
4.3.3 Create Maritime Entity

The interaction to create a new maritime entity (User, Service, Device or Vessel) within the Identity follows always the same procedure, therefore the following interaction diagram Figure 26 can be used for all entities. This step becomes obsolete, if the organization uses its own identity provider to manage their users. In this case the procedures of the individual identity provider has to be used. However, other maritime entities like vessels, devices and services have to be registered inside the Identity Registry to create certificates (see Figure 27) and to use the broker’s capability to evaluate certificates (see Figure 24).
If a maritime entity has been created, the Identity Registry, allows to create certificates for this entity. The sequence diagram to create a new certificate is shown in Figure 27. This step requires the user, to have the role of an organization administrator, within the Identity Registry (see. Table 1). As indicated through the optional “Create Entity” reference, this step can be performed on any existing maritime entity.
At this point, it’s worth to note, that the private keys, created together with the new certificate, can only be accessed while creating the certificate, for security reasons. The last sequence in Figure 27 (publish certificate) is a manual task, that has to be done by the organization administrator. This could for example mean, to copy the certificate to an USB device and manually install it on a vessel.
The following section describes the interactions to either discover service specifications, technical designs or service instance descriptions as well as the management of those. The corresponding sequence diagrams uses an optional reference to the “Authenticate User” sequence diagram (see Figure 23). This optional step has only to be performed on the first lookup, until the service user has its OpenID token.

4.3.4 Service discovery

Figure 28 interaction pattern to discover one or more service specifications

As described in Table 3 (SR API) the “getServiceSpecifications” method can take a search query for keywords, which have been provided, when the service specification has been published.
To get a technical design, the realized service specification id has to be known by the service user. If the specification id is already known, the optional “Discover Service Specification” step in Figure 29 may be omitted.

The second argument in the “getServiceTechnicals” represents the version of the Service Specification. If the second argument is left empty, the latest version is returned by the Service Registry.
Searching for a service instance description requires the service specification id and id of the technical design, implemented by that service. In addition an additional geographic location can be provided. The geometry has to be provided, using the Well Known Text (WKT) format, for example `Polygon((53.57 9.89, 53.57 10.06, 53.49 10.06, 53.49 9.89, 53.57 9.89))` if a list of service instances in the area of Hamburg (Germany) should be found.
4.3.5 Service publishing

The service specification that should be registered, contains different Meta information that should help to find the service, as described in Deliverable D3.6 (Service Specification Guidelines). This Meta information contains, among others, a list of keywords describing the service as well as the filled service specification template, as described in Deliverable D3.6.
Figure 32 Sequence diagram to publish a technical design in the Service Registry

To register a technical design, implementing a service specification, the corresponding service specification has to be known. If the specification (incl. version of service specification) is not known, the specification can be received using the optional “Discover Service Specification” sequence in advance of uploading the design document.
The sequence to register a service instance is similar to those to register a service specification and a technical design. However, if the service should be able to authenticate itself he can be registered in the Identity Registry as well. For this purpose the “Register Entity” Sequence has to be instantiated with a service as maritime entity.

To create a connection between the service within the Service Registry and the service within the Identity Registry, they have to be registered using the same Maritime Resource Name.

---

**Figure 33 Sequence diagram to publish a service instance description**

The sequence to register a service instance is similar to those to register a service specification and a technical design. However, if the service should be able to authenticate itself he can be registered in the Identity Registry as well. For this purpose the “Register Entity” Sequence has to be instantiated with a service as maritime entity.

To create a connection between the service within the Service Registry and the service within the Identity Registry, they have to be registered using the same Maritime Resource Name.
4.4 Deployment
The following Figure 34 shows one possible deployment diagram for the described Maritime Connectivity Platform components.

The deployment can be separated into 3 different types of deployment environments.

1) Maritime Connectivity Platform Environment
   The Maritime Connectivity Platform environment contains the Service and Identity Registry, as central parts of the Maritime Connectivity Platform architecture. Both may be hosted on different servers, with direct internet connection.

2) Client Environment
   The client environment may be located onboard of a vessel or onshore, on a standard computer, hosting the client application (e.g. an ECDIS or any other application, using the Maritime Connectivity Platform).

3) Service Environment
   External Services as well as external identity provider shall be hosted in their own environments, depending on their needs, e.g. a virtual server for an instance of Keycloak identity provider.
Figure 34 Deployment diagram for the described Maritime Connectivity Platform components

“This project has received funding from the European Union’s Horizon 2020 research and innovation programme under grant agreement No 636329.”
5 Application scenario

This final section provides an overview about the advanced development of the Maritime Connectivity Platform for practical usage. It contributes to the currently undertaken efforts within the three projects ES2, STM and Smart Navigation for harmonization of the different components of the Maritime Connectivity Platform for a future integration into existing maritime equipment.
